

Computer Arithmetic

Spring2015

Name:Vinay Chittam

Student ID:FET110

Project#1: CCA

Aim: For an n-bit Carry Completion Adder, write a C program to determine the relationship between the average delay and operand size (n).

Procedure: Consider the addition of two 4 bit numbers. A= 0 1 1 0 and B= 1 1 0 0. When the completion adder is performed, the following steps take place :

1. Like any other normal addition, the addition takes place from the right most bit. And every addition requires an incoming carry. The right most bits of A and B are 0,0. The incoming carry to these bits is 0. The incoming carry is always 0 for the addition of extreme right most bits. Since the incoming carry is 0, set $c_0 = 1$ and $c_1 = 0$ (acts like a switch). Set all the other incoming carries to other bits as $c_1 = 0$ and $c_0 = 0$ (switch is neither on nor off i.e not finalized). This entire cycle is "T0" which doesn't have any delay.
2. Now the previous incoming carry for extreme right most bit which set in the last cycle is used by the extreme right most bit to generate a carry out. i.e $0+0+0$ which again gives a $c_0 = 1$ and $c_1 = 0$ (i.e there is 0 carry). The last but one bit i.e the 3rd bit has an incoming carry that is not finalized , therefore the carryout is not finalized as well. For the second bit i.e A=1 and B=1, the incoming carry is not finalized, yet the carryout is $c_1 = 1$ (because when the two bits are 1 and 1, no matter what the incoming carry is, the carryout will always be 1). The first bit has an incoming carry which is not finalized, and since we have A=0 and B=1, the carryout is not finalized. This entire process is cycle "T1"
3. All the carryouts generated in cycle "T1" goes as carry in to the bits of A and B in cycle "T2". Here we try to finalize the bits, which were not finalized in the cycle "T1".
4. This process is continued till all the bits are finalized.
5. This process of addition can be simulated in C language. The code is given below.

Softwares used for simulation: C and microsoft excell.

C Program:

```
#include<stdio.h>
#include<conio.h>
#include<stdlib.h>
#include<alloc.h>
int k,*a,*b,*c0,*c1,*t0,*t1,i,j,n,s,m,l,td,flag;
long ttd;// variable to store delay
float avgd;// variable to store average delay

void set(){
```

```

for(j=0;flag==1 && j<=n;j++){

t1[j]=c1[j];

t0[j]=c0[j];

} // Set function is used to store all the carryout bits in a temporary array, which acts as carry-in bits
}

void bits(int *c0,int *c1,int *t0,int *t1){

//// bit function checks for all conditions possible and generates carry-out bits

for(i=n-1;i>=0;i--){

s=a[i]+b[i];

if(s==0){

c0[i]=1;

c1[i]=0;

}

else if(s>1){

c0[i]=0;

c1[i]=1;

}

else if(s==1){

if(t0[i+1]==t1[i+1]){

c0[i]=0;

c1[i]=0;

}

else{

m=s+t1[i+1];

if(m>1){

```

```

        c0[i]=0;
        c1[i]=1;
    }
    else if(m<=1){
        c0[i]=1;
        c1[i]=0;
    }
}

}

}

void main(){

    clrscr();

    for(n=2;n<=48;n++){
        ttd=0;
        a=(int *)malloc(n*sizeof(int)); // creates memory for the array to store the variable no of bits
        b=(int *)malloc(n*sizeof(int));
        c1=(int *)malloc((n+1)*sizeof(int));
        c0=(int *)malloc((n+1)*sizeof(int));
        t1=(int *)malloc((n+1)*sizeof(int));
        t0=(int *)malloc((n+1)*sizeof(int));

        for(l=0;l<1000;l++){ //for looping 1000
            td=0;
            for(i=0;i<n;i++){

```

```
a[i]=((rand())%2); // random bits will be stored in a[i]
b[i]=((rand())%2);
}
```

```
for(i=0;i<n;i++){
t1[i]=0; // initializing all the bits to 0
t0[i]=0; // initializing all the bits to 0
c1[i]=0;
    c0[i]=0;
}
```

```
t1[n]=0; // finalizing the carry –in bit, because the incoming carry will always be 0 so t1[n]=0
t0[n]=1;
    c1[n]=0;
    c0[n]=1;
```

```
do{
bits(c0,c1,t0,t1); // control goes to the function “bits()” and executes the logic there and returns
flag=0; // flag=0 means the carry outs are finalized
for(k=0;k<=n;k++){
    if(c0[k]==c1[k]){
        flag=1; // carry outs are not finalized
        set(); // calls the function “set()”
    }
}
```

```
if(flag==0){
td+=2; // calculation of delay for each cycle when bits are finalized
ttd+=td; // calculation of total delay
```

```
break;
}
else{
    ttd+=2;//calculation of delay when bits are not finalized
}
}
while(flag==1);

}

avgd=(float)ttd/1000;// calculation of average delay
printf("\ntotal delay for %dth bit number is %ld and average delay is %f",n,ttd,avgd);
}
getch();
}
```

Code Explanation:

1. Since we are asked to add two numbers of variable bit size from 2 to 48, I created for loop from $n=2$ to $n \leq 48$.
2. Then I created 6 pointer variables, a , b , $c0$, $c1$, $T0$, $T1$. (a and b hold the address of a memory location used to hold $n \times \text{size of int}$, which means if the number of bits 2, 4 bytes are allocated. Thus the size allocated depends on the value " n "). Similarly $c0$, $c1$, $T0$, $T1$ hold $(n+1) \times \text{size of int}$, which means $c0$, $T0$, $c1$ hold the address of memory location that can store $(n+1) \times \text{size of int}$. For example if $n=2$, then $c0$, $c1$, $T0$, $T1$ will have a memory of $3 \times 2 = 6$ bytes of memory.
3. We are required to take 1000 sets of random inputs to a and b . Therefore I created a for loop `for(l=0;l<1000;l++)` which iterates 1000 times and in each iteration $a[i]$ and $b[i]$ takes random input which are 1's and 0's. For this to happen, I made another for loop inside, which assigns random inputs to $a[i]$ and $b[i]$ using the random function "`rand()%2`". This for loop ends here, while the for loop for 1000 iteration still runs.
4. Inside the 1000 iteration for loop, I again created a for loop to initialize all the $c0[i]$, $c1[i]$, $T0[i]$ and $T1[i]$ to 0. This for loop has a condition that $i=0; i < n$. So all the values less than n will be 0. Outside the for loop $c0[n]=1, c1[n]=0, T0[n]=1$ and $T1[n]=0$ will be initialized (since the carry in for last bit is 0).
5. Next I created a do while loop. The body of `do{}` contains a function called `bits()`. In this function the main logic lies. For any addition, the operation takes place from the right most bit, so I created a for loop "`for(i=n-1;i>=0;i--)`", which starts from the last bit. The two last bits are added and stored in an array $s[i]$ (note that the addition is not xor, but it's a normal addition), and in this for loop I gave an if condition stating that if $s[i]=0$, the $c0[i]=1$ and $c1[i]=0$, and if $s[i]>1$, $c0[i]=0$ and $c1[i]=1$. If $s[i]=1$, and $T0[i+1] = T1[i+1]$, then $c0[i]=c1[i]=0$ i.e carry out is not finalized. ($T0$ and $T1$ are temporary bits which hold the carry in bits and $c0$ and $c1$ are the carry out bits). If $s[i] + T1[i+1] > 1$ then $c0[i]=0$ and $c1[i]=1$ and if $s[i] + T1[i+1] < 1$ then $c0[i]=1$ and $c1[i]=0$. Thus all the possible conditions are checked in this do loop.
6. To know if the carry out bits are finalized or not, I created a variable `flag=0`, which means says that the bits are finalized and if `flag=1` then they are not finalized. The flag should become 1 when the two bits $c1[k]$ and $c0[k]$ are equal to 0. So I gave that condition in a for loop and if it met flag becomes 1. The do loop executes while `flag=1` and doesn't execute when `flag=0`.
7. Then I call a function called `set()`. In `set` function I store the carry out bits in a temporary array, which act as carry-in bits for the bits in next cycle.
8. For one iteration i.e the 1000 iteration loop the delay for each cycle is calculated as $2d$ and added for all 1000 iterations. At the end of each iteration the calculated delay " td " is stored total time delay " ttd ". For example in the for loop `i=0;i<1000;i++`, for the first iteration $i=0$, the delay td is calculated. Say its $6d$. Then for the second iteration $i=1$, the delay td is again calculated and added to the previous delay td and stored in ttd . and this continues for all the iterations. The final value is divided by 1000 to get the average delay for n bits. (Note that n is again varying, so this process repeats for each value of n).

Output of the code:

```
total delay for 2th bit number is 2994 and average delay is 2.994000
total delay for 3th bit number is 3956 and average delay is 3.956000
total delay for 4th bit number is 4814 and average delay is 4.814000
total delay for 5th bit number is 5386 and average delay is 5.386000
total delay for 6th bit number is 5886 and average delay is 5.886000
total delay for 7th bit number is 6292 and average delay is 6.292000
total delay for 8th bit number is 6706 and average delay is 6.706000
total delay for 9th bit number is 7030 and average delay is 7.030000
total delay for 10th bit number is 7462 and average delay is 7.462000
total delay for 11th bit number is 7636 and average delay is 7.636000
total delay for 12th bit number is 7924 and average delay is 7.924000
total delay for 13th bit number is 8172 and average delay is 8.172000
total delay for 14th bit number is 8296 and average delay is 8.296000
total delay for 15th bit number is 8568 and average delay is 8.568000
total delay for 16th bit number is 8634 and average delay is 8.634000
total delay for 17th bit number is 8990 and average delay is 8.990000
total delay for 18th bit number is 9066 and average delay is 9.066000
total delay for 19th bit number is 9214 and average delay is 9.214000
total delay for 20th bit number is 9324 and average delay is 9.324000
total delay for 21th bit number is 9498 and average delay is 9.498000
total delay for 22th bit number is 9710 and average delay is 9.710000
total delay for 23th bit number is 9686 and average delay is 9.686000
total delay for 24th bit number is 9980 and average delay is 9.980000_
```

```
total delay for 24th bit number is 9980 and average delay is 9.980000
total delay for 25th bit number is 10134 and average delay is 10.134000
total delay for 26th bit number is 10070 and average delay is 10.070000
total delay for 27th bit number is 10232 and average delay is 10.232000
total delay for 28th bit number is 10396 and average delay is 10.396000
total delay for 29th bit number is 10480 and average delay is 10.480000
total delay for 30th bit number is 10558 and average delay is 10.558000
total delay for 31th bit number is 10642 and average delay is 10.642000
total delay for 32th bit number is 10758 and average delay is 10.758000

total delay for 46th bit number is 11802 and average delay is 11.802000
total delay for 47th bit number is 11924 and average delay is 11.924000
total delay for 48th bit number is 12092 and average delay is 12.092000_
```

The output of program

Total delay and average delay for bits varying from 2 to 48.

Observation: It can be observed that as the number of bits increases, the average delay increases. Operand size and average delay have a linear relationship. This can be shown clearly in the graph. I used the data and plotted the graph in Microsoft Excel.

Figure showing the plot between Average Delay and Operand Size (n)

C program for n=24 bit pattern: A= 101001001100101101100101 and B=0101011111000010010001011

total delay for 24th bit number is 16d_
```

The output of c program for 24bit patter. It takes 16d to finalize all the carry out bits.

Conclusion:

In each cycle some bits are finalized in parallel and some bits are not finalized. The bits that are finalized in a cycle are given as carry-in to A and B in the next cycle(This can be achieved by using a temporary array $t0[i]$ and $t1[i]$). This process continues till all the $c0$ and $c1$ bits are finalized. It takes 8 cycles to finalize all the bits in $c0$ and $c1$, and each cycle takes $2d$ delay. Therefore the total delay is $2d \cdot 8 = 16d$.

Although in each cycle some bits such as $A=0$ and $B=0$ or $A=1$ and $B=1$ parallelly generates the carry irrespective of the incoming carry it can be clearly noticed that when the number of bits " n " is more, it takes more cycles to finalize all the bits because when $A=1$ and $B=0$ or vice versa the incoming carry is to be finalized to generate a carryout.

Similarly when the number of bits is less, all the bits get finalized in very few cycles.
